

# Mis-Classified, Binary, Endogenous Regressors: Identification and Inference

Francis J. DiTraglia<sup>1</sup>   Camilo García-Jimeno<sup>2,3</sup>

<sup>1</sup>University of Pennsylvania

<sup>2</sup>Emory University

<sup>3</sup>NBER

October 11th, 2018

- Thank you for inviting me. Joint work with Camilo Garcia-Jimeno.
- Intro. 'metrics students learn that a valid IV serves double duty: correct for endogeneity and classical measurement error
- Classical measurement error is a special case: requires true value of regressor indep. of or at least uncorrelated with measurement error
- Applied work often involves endogenous binary regressor: smoker/non-smoker or union/non-union. Binary  $\implies$  non-classical error. True 0  $\implies$  can only mis-measure *upwards* as 1; true 1  $\implies$  can only mis-measure *downwards* as 0. Error *negatively correlated* with truth.
- To accommodate this, consider *non-diff* error. Say more later, but roughly non-diff means *conditionally classical*: condition on truth and controls, remaining component of error unrelated to everything else.
- Today pose simple question: binary, endog. regressor subject to non-diff. error. Can valid IV correct for *both* measurement error and endog?

## What is the effect of $T^*$ ?

$$y = c(\mathbf{x}) + \beta(\mathbf{x})T^* + \varepsilon$$

- ▶  $y$  – Outcome of interest
- ▶  $T^*$  – Unobserved, endogenous binary regressor
- ▶  $T$  – Observed, mis-measured binary surrogate for  $T^*$
- ▶  $\mathbf{x}$  – Exogenous covariates
- ▶  $z$  – Discrete (typically binary) instrumental variable

$$y = c(x) + \beta(x)T^* + \varepsilon$$

- $y$  = Outcome of interest
- $T^*$  = Unobserved, endogenous binary regressor
- $T$  = Observed, mis-measured binary surrogate for  $T^*$
- $x$  = Exogenous covariates
- $z$  = Discrete (typically binary) instrumental variable

└ What is the effect of  $T^*$ ?

- Here is the specific model I will focus on today. Additively separable model, want to learn the causal effect of binary regressor  $T^*$  on  $y$ . Unfortunately  $T^*$  is unobserved. Observe only mis-measured binary surrogate  $T$ . To make matters worse,  $T^*$  is endogenous, but we have a discrete instrument  $z$ .
- Additive separability is an assumption. Allow very general forms of observed heterogeneity through  $x$  but restricts unobserved heterogeneity.
- Conditionally linear model. This is without loss of generality since the model is additively separable and  $T^*$  is binary.
- Mainly focus on additively separable case today, but will also discuss implications of our results for a LATE model.

## Using a discrete IV to learn about $\beta(\mathbf{x})$

$$y = c(\mathbf{x}) + \beta(\mathbf{x})T^* + \varepsilon$$

### Contributions of This Paper

1. Show that only existing point identification result for mis-classified, endogenous  $T^*$  is incorrect.
2. Sharp identified set for  $\beta$  under standard assumptions.
3. Point identification of  $\beta$  under slightly stronger assumptions.
4. Describe problem of weak identification in mis-classification models, develop identification-robust inference for  $\beta$ .

$$y = c(\mathbf{x}) + \beta(\mathbf{x})T^* + \varepsilon$$

## Contributions of This Paper

1. Show that only existing point identification result for mis-classified, endogenous  $T^*$  is incorrect.
2. Sharp identified set for  $\beta$  under standard assumptions.
3. Point identification of  $\beta$  under slightly stronger assumptions.
4. Describe problem of weak identification in mis-classification models, develop identification-robust inference for  $\beta$ .

## └ Using a discrete IV to learn about $\beta(\mathbf{x})$

- Here are the main contributions of paper that I will discuss today.
- Many papers consider using IV to identify effect of exog. mis-measured binary regressor, but little work on endog. case. First: show only point identification result for this case incorrect: ident. is an open question.
- Next: use standard assumptions to derive the “sharp identified set” for  $\beta$ . This means *fully* exploit all information in the data and our assumptions to derive tightest possible bounds for  $\beta$ . If bounds contain a single point,  $\beta$  is point identified. Otherwise partially identified.
- Novel and informative bounds for  $\beta$ , but not point identified. Then consider slightly stronger assumptions that allow us to exploit additional features of the data and show that these suffice to point identify  $\beta$ .
- Next consider inference. Show that mis-classification models, suffer from potential weak identification. Propose procedure for robust inference.
- Now a motivating example. . .

# Example: Smoking and Birthweight (SNAP Trial)

Coleman et al. (N Engl J Med, 2012)

RCT with pregnant smokers in England: half given nicotine patches, the rest given placebo patches. Some given nicotine fail to quit; some given placebo quit.

- ▶  $y$  – Birthweight
- ▶  $T^*$  – True smoking behavior
- ▶  $T$  – Self-reported smoking behavior
- ▶  $x$  – Mother characteristics
- ▶  $z$  – Indicator of nicotine patch

# Binary Regressors

## Example: Smoking and Birthweight (SNAP

Example: Smoking and Birthweight (SNAP Trial)

Coleman et al. (N Engl J Med, 2012)

RCT with pregnant smokers in England: half given nicotine patches, the rest given placebo patches. Some given nicotine fail to quit; some given placebo quit.

- $y$  = Birthweight
- $T^*$  = True smoking behavior
- $T$  = Self-reported smoking behavior
- $x$  = Mother characteristics
- $z$  = Indicator of nicotine patch

# Baseline Assumptions I – Model & Instrument

## Additively Separable Model

$$y = c(\mathbf{x}) + \beta(\mathbf{x})T^* + \varepsilon, \quad \mathbb{E}[\varepsilon] = 0$$

## Valid & Relevant Instrument: $z \in \{0, 1\}$

- ▶  $\mathbb{P}(T^* = 1 | \mathbf{x}, z = 1) \neq \mathbb{P}(T^* = 1 | \mathbf{x}, z = 0)$
- ▶  $\mathbb{E}[\varepsilon | \mathbf{x}, z] = 0$
- ▶  $0 < \mathbb{P}(z = 1 | \mathbf{x}) < 1$

## └ Baseline Assumptions I – Model & Instrument

Additively Separable Model

$$y = c(\mathbf{x}) + \beta(\mathbf{x})T^* + \varepsilon, \quad \mathbb{E}[\varepsilon] = 0$$

Valid & Relevant Instrument:  $z \in \{0, 1\}$

- $\mathbb{P}(T^* = 1 | \mathbf{x}, z = 1) \neq \mathbb{P}(T^* = 1 | \mathbf{x}, z = 0)$
- $\mathbb{E}[\varepsilon | \mathbf{x}, z] = 0$
- $0 < \mathbb{P}(z = 1 | \mathbf{x}) < 1$

- This is an econometrics talk so there will unavoidably be some lists of assumptions! But I want to make sure it's clear what each group of assumptions is actually doing.
- This slide and the text one detail what I will call the “baseline” assumptions, which I will maintain through the talk.
- The first part of the baseline assumptions concern the model and instrument: all that this slide says is that if  $T^*$  were observed, then the model would be identified.
- In particular, these conditions are simply the usual instrument relevance and validity conditions in the model with the true, unobserved regressor  $T^*$ .

# Baseline Assumptions II – Measurement Error

## Notation

►  $\alpha_0(\mathbf{x}, z) \equiv \mathbb{P}(T = 1 | T^* = 0, \mathbf{x}, z)$

►  $\alpha_1(\mathbf{x}, z) \equiv \mathbb{P}(T = 0 | T^* = 1, \mathbf{x}, z)$

## Mis-classification unaffected by $z$

$$\alpha_0(\mathbf{x}, z) = \alpha_0(\mathbf{x}), \quad \alpha_1(\mathbf{x}, z) = \alpha_1(\mathbf{x})$$

## Extent of Mis-classification

$$\alpha_0(\mathbf{x}) + \alpha_1(\mathbf{x}) < 1 \quad (T \text{ is positively correlated with } T^*)$$

## Non-differential Mis-classification

$$\mathbb{E}[\varepsilon | \mathbf{x}, z, T^*, T] = \mathbb{E}[\varepsilon | \mathbf{x}, z, T^*]$$

## Notation

- $\alpha_0(\mathbf{x}, z) = \mathbb{P}(T = 1 | T^* = 0, \mathbf{x}, z)$
- $\alpha_1(\mathbf{x}, z) = \mathbb{P}(T = 0 | T^* = 1, \mathbf{x}, z)$

Mis-classification unaffected by  $z$ 

$$\alpha_0(\mathbf{x}, z) = \alpha_0(\mathbf{x}), \quad \alpha_1(\mathbf{x}, z) = \alpha_1(\mathbf{x})$$

## Extent of Mis-classification

$$\alpha_0(\mathbf{x}) + \alpha_1(\mathbf{x}) < 1 \quad (T \text{ is positively correlated with } T^*)$$

## Non-differential Mis-classification

$$\mathbb{E}[y | \mathbf{x}, z, T^*, T] = \mathbb{E}[y | \mathbf{x}, z, T^*]$$

## └ Baseline Assumptions II – Measurement Error

- 2nd part of the baseline assumptions concerns measurement error process. First need some notation: mis-classification probs.  $\alpha_0$  and  $\alpha_1$ . Two possible errors. *Upwards* mis-classification: observe  $T = 1$  when truth is  $T^* = 1$ . This occurs with prob.  $\alpha_0$ . *Downwards* mis-classification: observe  $T = 0$  when truth is  $T^* = 1$ . This occurs with prob.  $\alpha_1$ . Convention uses subscripts to indicate the value of *truth*:  $\alpha_0$  is mis-classification prob. when  $T^* = 0$  ( $\uparrow$ ) and  $\alpha_1$  when  $T^* = 1$  ( $\downarrow$ ). So far notation: now restrictions
- First: given  $\mathbf{x}$  the mis-class. rates don't depend on  $z$ . Restrictive, but hard to make progress without it. How reasonable depends on  $\mathbf{x}$  and specific setting. Plausible: smoking mothers didn't know if they had the real or placebo patch. Implausible: Levitt coin-toss experiment. Does making a big life change (e.g. quit job) make you happier? People considering big change flip a coin: heads = Levitt tells you to change, tails = he doesn't. Here  $T^* =$  did you really change and  $T =$  self-report. People who were told to change to but didn't ( $z = 1, T^* = 0$ ) more likely have  $T = 0$  than people who weren't told to change and didn't ( $z = 0, T^* = 0$ )
- Second:  $\text{Cor}(T, T^*) > 0 \iff \alpha_0 + \alpha_1 < 1$ . Mild assumption. I'll say more in a few slides.
- Third: *non-diff* assumption. Stated in terms of epsilon, but what this really requires is conditional mean of  $Y$  doesn't depend on  $T$  given  $(\mathbf{x}, z, T^*)$ . Plausibility depends on the situation and the controls in  $\mathbf{x}$ . Example of what this rules out: "returns to lying." E.g.  $Y = \log(\text{wage})$ ,  $T^* =$  true college dummy, and  $T =$  self-report of college. If employers can't perfectly observe credentials, there could be a *direct* effect of  $T$  on  $y$  even after controlling for  $T^*$ . Working on a paper based on this example with Arthur Lewbel.

# Existing Results

## Correct: Exogenous $T^*$

- ▶ Mahajan (2006), Frazis & Loewenstein (2003)
- ▶  $\mathbb{E}[\varepsilon|\mathbf{x}, z, T^*] = 0$  + “Baseline”  $\Rightarrow \beta(\mathbf{x})$  identified.

## Incorrect: Endogenous $T^*$

- ▶ Mahajan (2006) A.2
- ▶  $\mathbb{E}[\varepsilon|\mathbf{x}, z, T^*, T] = \mathbb{E}[\varepsilon|\mathbf{x}, T^*] + \text{“Baseline”} \Rightarrow \beta(\mathbf{x})$  identified.

We show: Mahajan's assumptions imply that the instrument  $z$  is uncorrelated with  $T^*$  unless  $T^*$  is in fact *exogenous*.

## Existing Results

### Existing Results

#### Correct: Exogenous $T^*$

- Mahajan (2006), Frazis & Loewenstein (2003)
- $E[y|x, z, T^*] = 0 + \text{"Baseline"} \Rightarrow \beta(x) \text{ identified.}$

#### Incorrect: Endogenous $T^*$

- Mahajan (2006) A.2
- $E[y|x, z, T^*] = E[y|x, T^*] + \text{"Baseline"} \Rightarrow \beta(x) \text{ identified.}$

We show: Mahajan's assumptions imply that the instrument  $z$  is uncorrelated with  $T^*$  unless  $T^*$  is in fact exogenous.

- Two results from the existing literature closely related to our own: one for *exogenous*  $T^*$ , and one for *endogenous*  $T^*$ . Exogenous case: various papers have looked at this, but most general and closest to how I've set things up above is a result in Mahajan (2006). Similar although less general result in Frazis & Loewenstein (2003). Baseline assumptions plus a *joint exogeneity condition* for  $T^*$  and  $z$  point identify  $\beta$ . Notice that if you're interested in a conditional mean function rather than a causal effect, additive separability and exogeneity of  $T^*$  come for free. Estimator is *not* IV, but non-linear GMM estimator.
- The only existing result for the *endogenous*  $T^*$  case also appears in Mahajan. To be fair, this is *not* the main point of his paper, which primarily concerns the exogenous case. Mahajan argues that the baseline conditions plus a somewhat exotic-looking condition here implies that  $\beta$  is point identified. The purpose of this additional condition is to create a link with his earlier result for the exogenous case. Idea is as follows:  $\alpha_0$  and  $\alpha_1$  have the same meaning regardless of whether you are estimating a conditional mean model or a causal model. Try to recover  $(\alpha_0, \alpha_1)$  using the exogenous  $T^*$  result, and then "plug them in" in a second step. This strategy relies on the additional assumption.
- First contribution: we show that Mahajan's assumptions imply that  $z$  is *irrelevant*, uncorrelated with  $T^*$ , *unless*  $T^*$  is *exogenous*. Mahajan's argument for the endogenous  $T^*$  fails; identification is an open question.

# “Weak” Bounds

## First-Stage

$$p_k(\mathbf{x}) \equiv \mathbb{P}(T = 1 | \mathbf{x}, z = k)$$

## IV Estimand

$$\frac{\mathbb{E}[y | \mathbf{x}, z = 1] - \mathbb{E}[y | \mathbf{x}, z = 0]}{p_1(\mathbf{x}) - p_0(\mathbf{x})} = \frac{\beta(\mathbf{x})}{1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})}$$

## Bounds for $(\alpha_0, \alpha_1)$

$$\alpha_0(\mathbf{x}) \leq \min_k \{p_k(\mathbf{x})\}, \quad \alpha_1(\mathbf{x}) \leq \min_k \{1 - p_k(\mathbf{x})\} \quad \text{▶ more}$$

## Bounds for $\beta$

$\beta(\mathbf{x})$  is between IV and Reduced form; same sign as IV. ▶ more

# Binary Regressors

└ “Weak” Bounds

“Weak” Bounds

First-Stage

$$\rho_k(\mathbf{x}) = \mathbb{P}(T = 1 | \mathbf{x}, z = k)$$

IV Estimand

$$\frac{\mathbb{E}[y | \mathbf{x}, z = 1] - \mathbb{E}[y | \mathbf{x}, z = 0]}{\rho_1(\mathbf{x}) - \rho_0(\mathbf{x})} = \frac{\beta(\mathbf{x})}{1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})}$$

Bounds for  $(\alpha_0, \alpha_1)$

$$\alpha_0(\mathbf{x}) \leq \min_k \{\rho_k(\mathbf{x})\}, \quad \alpha_1(\mathbf{x}) \leq \min_k \{1 - \rho_k(\mathbf{x})\}$$

Bounds for  $\beta$

$\beta(\mathbf{x})$  is between IV and Reduced form; same sign as IV

Add some notes here. . .

- Describe the picture. Explain how the upper-right corner of the blue rectangle corresponds to the reduced form estimator and the lower-left to the IV estimator. Explain  $\alpha_0 + \alpha_1 < 1$  in relation to the gray rectangle and red line.
- Weak bounds for  $(\alpha_0, \alpha_1, \beta)$  simple and informative. Others have used related idea: Frazis & Loewenstein (2003) and Ura (forthcoming). But weak bounds don't use non-diff assumpt. Know that non-diff is powerful: point identifies effect of an exog  $T^*$ . Can we improve upon weak bounds for endog.  $T^*$ ?
- To answer this, derive sharp identified set under baseline assumptions: new to the literature. Important even if our main concern is point identification: while we showed a flaw in Mahajan's proof, we did *not* demonstrate
- How to derive sharp set? Question: for what values of unknown params can we construct valid joint dist. for  $(y, T, T^*, z)$  compatible with observed joint for  $(y, T, z)$  under our assumptions? Factorize: joint for  $(T, T^*, z)$  & conditional for  $y|T, T^*, z$ . Turns out that weak bounds for  $(\alpha_0, \alpha_1)$  ensure valid joint for  $(T, T^*, z)$  so suffices to look at conditional:  $y|T, T^*, z$ .

# Restrictions from Non-differential Mis-classification?

(Suppress  $\mathbf{x}$  for simplicity)

## Notation

- ▶  $r_{tk} \equiv \mathbb{P}(T^* = 1 | T = t, z = k)$
- ▶  $z_k$  is shorthand for  $z = k$

## Iterated Expectations over $T^*$

$$\mathbb{E}(y | T = 0, z_k) = (1 - r_{0k})\mathbb{E}(y | T^* = 0, T = 0, z_k) + r_{0k}\mathbb{E}(y | T^* = 1, T = 0, z_k)$$

$$\mathbb{E}(y | T = 1, z_k) = (1 - r_{1k})\mathbb{E}(y | T^* = 0, T = 1, z_k) + r_{1k}\mathbb{E}(y | T^* = 1, T = 1, z_k)$$

# Restrictions from Non-differential Mis-classification?

(Suppress  $\mathbf{x}$  for simplicity)

## Notation

- ▶  $r_{tk} \equiv \mathbb{P}(T^* = 1 | T = t, z = k)$
- ▶  $z_k$  is shorthand for  $z = k$

## Adding Non-differential Assumption

$$\mathbb{E}(y | T = 0, z_k) = (1 - r_{0k})\mathbb{E}(y | T^* = 0, z_k) + r_{0k}\mathbb{E}(y | T^* = 1, z_k)$$

$$\mathbb{E}(y | T = 1, z_k) = (1 - r_{1k})\mathbb{E}(y | T^* = 0, z_k) + r_{1k}\mathbb{E}(y | T^* = 1, z_k)$$

2 equations in 2 unknowns $\Rightarrow$ solve for $\mathbb{E}(y   T^* = t^*, z = k)$ given $(r_{0k}, r_{1k})$ .
---

## └ Restrictions from Non-differential

Restrictions from Non-differential Mis-classification?

(Suppress  $x$  for simplicity)

## Notation

- $\pi_k = P(T^* = 1 | T = t, x = k)$
- $z_k$  is shorthand for  $x = k$

## Adding Non-differential Assumption

$$\begin{aligned} E(y | T = 0, x_k) &= (1 - \pi_k) E(y | T^* = 0, x_k) &+ \pi_k E(y | T^* = 1, x_k) \\ E(y | T = 1, x_k) &= (1 - \pi_k) E(y | T^* = 0, x_k) &+ \pi_k E(y | T^* = 1, x_k) \end{aligned}$$

2 equations in 2 unknowns  $\Rightarrow$  solve for  $E(y | T^* = t^*, x = k)$  given  $(\pi_k, \pi_{1k})$ 

- Suppress dependence on  $x$ . Study conditional dist of  $y | T, T^*, z$ . Unobserved but related to dist of  $y | T, z$  via a mixture model. Mixing probs are  $r_{tk}$ . These turn out to be a function of  $(\alpha_0, \alpha_1)$  and observables only. Shorthand:  $z_k$  denotes  $z = k$ .
- First look at means. For each value  $k$  that the IV takes on, there are two observed means  $E[y | T = (0, 1), z_k]$  and four unobserved means  $E[y | T = (0, 1), T^* = (0, 1), z_k]$ . But the non-diff assumption restricts the four unobserved means: we can *drop*  $T$  from the conditioning set after conditioning on  $T^*, z$ . Hence, only two unknown means: color-coded to show common unknowns across equations.
- Remember:  $r_{tk}$  is known given  $(\alpha_0, \alpha_1)$ , so we see that the non-diff. assumption lets us solve for the two unknown means at any specified pair  $(\alpha_0, \alpha_1)$ : we simply have two linear equations in two unknowns.

# Restrictions from Non-differential Mis-classification?

## Mixture Representation

$$F_{tk} = (1 - r_{tk})F_{tk}^0 + r_{tk}F_{tk}^1$$

$$F_{tk} \equiv y | (T = t, z = k)$$

$$F_{tk}^{t^*} \equiv y | (T^* = t^*, T = t, z = k)$$

## Restrictions

- ▶  $\mathbb{E}(y | T^*, T, z) = \mathbb{E}(y | T^*, z)$  observable given  $(\alpha_0, \alpha_1)$
- ▶  $r_{tk}$  observable given  $(\alpha_0, \alpha_1)$

## Question

Given  $(\alpha_0, \alpha_1)$  can we always find  $(F_{tk}^0, F_{tk}^1)$  to satisfy the mixture model?

## └ Restrictions from Non-differential

## Mixture Representation

$$F_{ik} = (1 - r_{ik})F_{ik}^0 + r_{ik}F_{ik}^1$$

$$r_{ik} = p(T = t, z = k)$$

$$r_{ik}^c = p(T^c = t^c, T = t, z = k)$$

## Restrictions

- $\mathbb{E}(y|T^c, T, z) = \mathbb{E}(y|T^c, z)$  observable given  $(\alpha_0, \alpha_1)$
- $r_{ik}$  observable given  $(\alpha_0, \alpha_1)$

## Question

Given  $(\alpha_0, \alpha_1)$  can we always find  $(F_{ik}^0, F_{ik}^1)$  to satisfy the mixture model?

- Looked at means, now look at distributions. Observe  $F_{tk}$  the distribution of  $y|T, z$ . This is a mixture of two unobserved distributions:  $F_{tk}^0$  and  $F_{tk}^1$ .
- Although  $(F_{tk}^0, F_{tk}^1)$  are unobserved, they're constrained. First, they need to "integrate" to  $F_{tk}$  which is observed. Second, the mixing probability  $r_{tk}$  is a *known* function of  $(\alpha_0, \alpha_1)$  given observables. Third, as we saw on the preceding slide, non-differential measurement error implies that the means of  $F_{tk}^0$  and  $F_{tk}^1$  are *known* functions of  $(\alpha_0, \alpha_1)$ .
- Given these constraints, can we find valid distributions  $(F_{tk}^0, F_{tk}^1)$  to satisfy the mixture representation for *any pair*  $(\alpha_0, \alpha_1)$ ? Or are there some values for the mis-classification probabilities that are incompatible with the mixture model?

# Restrictions from Non-differential Mis-classification?

## Equivalent Problem

Given a specified CDF  $F$ , for what values of  $p$  and  $\mu$  do there exist valid CDFs  $(G, H)$  with  $F = (1 - p)G + pH$  and  $\mu = \text{mean}(H)$ ?

## Necessary and Sufficient Condition if $F$ is Continuous

$$\underline{\mu}(F, p) \leq \mu \leq \bar{\mu}(F, p)$$

$$\underline{\mu}(F, p) \equiv \int_{-\infty}^{\infty} x \left[ p^{-1} f(x) \mathbf{1}\{x < F^{-1}(p)\} \right] dx = \int_{-\infty}^{\infty} x \underline{h}(x) dx$$

$$\bar{\mu}(F, p) \equiv \int_{-\infty}^{\infty} x \left[ p^{-1} f(x) \mathbf{1}\{x > F^{-1}(1 - p)\} \right] dx = \int_{-\infty}^{\infty} x \bar{h}(x) dx$$

## Equivalent Problem

Given a specified CDF  $F$ , for what values of  $p$  and  $\mu$  do there exist valid CDFs  $(G, H)$  with  $F = (1 - p)G + pH$  and  $\mu = \text{mean}(H)$ ?

Necessary and Sufficient Condition if  $F$  is Continuous

$$\mu(F, p) \leq \mu \leq \bar{\mu}(F, p)$$

$$\mu(F, p) = \int_{-\infty}^{\infty} x [p^{-1}f(x)\mathbb{I}(x < F^{-1}(p))] dx = \int_{-\infty}^{\infty} x \underline{g}(x) dx$$

$$\bar{\mu}(F, p) = \int_{-\infty}^{\infty} x [p^{-1}f(x)\mathbb{I}(x > F^{-1}(1-p))] dx = \int_{-\infty}^{\infty} x \bar{g}(x) dx$$

## Restrictions from Non-differential

- To answer this question, we need to answer a more abstract question about mixture distributions. In particular, suppose that we observe a distribution  $F$ . Can we construct valid distributions  $(G, H)$  such that  $F$  is a mixture of  $G$  and  $H$  in which  $H$  has mixing weight  $p$  and mean  $\mu$ ?
- To be clear: in this exercise  $F$  is fixed. The question is: if I postulate a mixing probability  $p$  and a mean  $\mu$  for one of the mixture components, can this ever lead to a contradiction? Are we free to pick any pair  $(p, \mu)$  or does the observed distribution  $F$  tie our hands?
- It turns out that if  $y$  is continuously distributed, one can derive relatively simple necessary and sufficient conditions using a first-order stochastic dominance argument.
- In particular: for any fixed  $(F, p)$  there is a lower bound  $\underline{\mu}$  and an upper bound  $\bar{\mu}$  within which the postulated mean  $\mu$  *must* lie, for it to be possible to construct a valid mixture. These lower and upper bounds are in fact expectations taken with respect to densities constructed by *truncating*  $F$ .
- Rather than staring at these integrals, let's look at a simple example.

## Binary Regressors

- This picture has three panels. The middle panel shows the observed distribution  $f$ . I have chosen a simple mixture of normals with variance equal to one: 70% of the weight is assigned to the one with a mean of  $-2$  and 30% to the one with a mean of  $+2$ .
- The top panel depicts the “lower bound” density  $\underline{h}$ . This density takes its shape from the *lower tail* of  $f$ . It is simply  $f$  *truncated* to take on values below its  $p$ th quantile.
- The bottom panel depicts the “upper bound” density  $\bar{h}$ . This density takes its shape from the *upper tail* of  $f$ . It is simply  $f$  *truncated* to take on values above its  $(1 - p)$ th quantile.
- For this particular choice of observed distribution  $f$ , the figure shows how a particular postulated value of  $p$ , in this instance 0.1, constrains  $\mu$ : it is bounded below by  $\underline{\mu} = -3.58$  and bounded above by  $\bar{\mu} = 3.09$ . This means that if  $p = 0.1$ , then  $\mu$  must lie between  $-3.58$  and  $3.09$  for it to be possible to construct a valid mixture that “integrates” to  $f$ . As we increase  $p$ , these bounds tighten, so we have less freedom in our choice of  $\mu$ .

- For this particular choice of  $f$ , a mixture of normals, the blue shaded region shows all pairs  $(p, \mu)$  that are compatible with the mixture.
- If  $p = 0$ ,  $\mu$  is unconstrained. This makes sense: in this case  $H$  can have any mean because it contributes nothing to the mixture that generates  $F$ .
- In contrast, if  $p = 1$  then  $\mu$  must *equal* the mean of the observed distribution  $F$ , in this case  $-0.8$ , since this corresponds to a degenerate mixture in which  $F = H$ .
- So how does this relate to our original problem? Remember that we observe the distribution of  $y|T, z$  which is related to the unobserved distribution of  $y|T, T^*, z$  via a mixture model. The mixing probability depends only on observables and  $(\alpha_0, \alpha_1)$  as do the means of the mixture components. Hence, some values of  $(\alpha_0, \alpha_1)$  are incompatible with the mixture model. This in turn restricts  $\beta$  through its relationship to the IV estimand. In fact we have *joint* restrictions for all  $(t, k)$  so the book-keeping is complicated, but the basic intuition is exactly as I've shown you in this simple mixture of normals example.

# Sharp Identified Set under Baseline Assumptions

## Theorem

- (i) If  $\mathbb{E}[y|\mathbf{x}, T = 0, z = k] \neq \mathbb{E}[y|\mathbf{x}, T = 1, z = k]$  for some  $k$ , non-differential assump. strictly improves upon weak bounds.
- (ii) Under the baseline assumptions,  $\beta$  is not point identified, regardless of how many (discrete) values  $z$  takes on.

## Corollary

Bounds for  $\alpha_0, \alpha_1$ , and  $\beta$  remain valid in a LATE model. They may not be sharp, however, sharp, since they do not incorporate the testable implications of the LATE assumptions.

## └ Sharp Identified Set under Baseline

### Theorem

- (i) If  $\mathbb{E}[y|x, T = 0, z = k] \neq \mathbb{E}[y|x, T = 1, z = k]$  for some  $k$ , non-differential assum. strictly improves upon weak bounds.
- (ii) Under the baseline assumptions,  $\beta$  is not point identified, regardless of how many (discrete) values  $z$  takes on.

### Corollary

Bounds for  $\alpha_0, \alpha_1$ , and  $\beta$  remain valid in a LATE model. They may not be sharp, however, sharp, since they do not incorporate the testable implications of the LATE assumptions.

- Second main contribution: sharp identified set for  $(\alpha_0, \alpha_1, \beta)$  under the baseline assumptions. The description of the set is fairly complicated, so I'm not going to show it on the slide. But the form that this set takes leads to two important results. First, the non-differential measurement error assumption *generically* improves upon the weak bounds. Second, under the baseline assumptions  $\beta$  is *never* point identified, regardless of how many different (discrete) values  $z$  takes.
- Some intuition: the true  $\beta$  always lies within the identified set by definition. It turns out that  $\alpha_0 = \alpha_1 = 0$  implies that the mixing probabilities  $r_{tk}$  are all either zero or one. But in this case the mixtures are trivial, so we can simply set  $F = H$ . Hence, the IV estimand always lies in the sharp identified set.
- Corollary: everything I've said so far concerns an additively separable model. But in fact, bounds we derive under the baseline assumptions remain valid if we re-state our assumptions so that they involve a LATE model. These bounds may not be sharp in a LATE model, however, because the LATE assumptions themselves have testable implications. We don't impose these since we're mainly interested in the additively separable case.
- What now? Sharp bounds quite informative in practice, but they do not point identify  $\beta$ . Baseline assumptions aren't enough. Are there slightly stronger but still plausible assumptions that allow us to point identify  $\beta$ ? Yes!

# Point Identification: 1st Ingredient

## Reparameterization

$$\theta_1(\mathbf{x}) = \beta(\mathbf{x}) / [1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})]$$

$$\theta_2(\mathbf{x}) = [\theta_1(\mathbf{x})]^2 [1 + \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})]$$

$$\theta_3(\mathbf{x}) = [\theta_1(\mathbf{x})]^3 \left[ \{1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})\}^2 + 6\alpha_0(\mathbf{x}) \{1 - \alpha_1(\mathbf{x})\} \right]$$

## Lemma

Baseline Assumptions  $\implies \text{Cov}(y, z|\mathbf{x}) = \theta_1(\mathbf{x})\text{Cov}(z, T|\mathbf{x})$ .

## Binary Regressors

## └ Point Identification: 1st Ingredient

Note that  $\beta = 0$  iff  $\theta_1 = \theta_2 = \theta_3 = 0$ .

Point Identification: 1st Ingredient

Reparameterization

$$\theta_1(\mathbf{x}) = \beta(\mathbf{x}) / [1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})]$$

$$\theta_2(\mathbf{x}) = [\theta_1(\mathbf{x})]^2 [1 + \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})]$$

$$\theta_3(\mathbf{x}) = [\theta_1(\mathbf{x})]^3 \left[ (1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x}))^2 + 6\alpha_0(\mathbf{x}) (1 - \alpha_1(\mathbf{x})) \right]$$

Lemma

Baseline Assumptions  $\implies \text{Cov}(y, z|\mathbf{x}) = \theta_1(\mathbf{x})\text{Cov}(z, T|\mathbf{x})$ .

## Point Identification: 2nd Ingredient

### Assumption (II)

$$\mathbb{E}[\varepsilon^2|\mathbf{x}, z] = \mathbb{E}[\varepsilon^2|\mathbf{x}]$$

### Lemma

(Baseline) + (II)  $\implies$

$$\text{Cov}(y^2, z|\mathbf{x}) = 2\text{Cov}(yT, z|\mathbf{x})\theta_1(\mathbf{x}) - \text{Cov}(T, z|\mathbf{x})\theta_2(\mathbf{x})$$

### Corollary

(Baseline) + (II) +  $[\beta(\mathbf{x}) \neq 0] \implies [\alpha_1(\mathbf{x}) - \alpha_0(\mathbf{x})]$  is identified.

## Binary Regressors

## └ Point Identification: 2nd Ingredient

Point Identification: 2nd Ingredient

Assumption (II)

$$\mathbb{E}[z^2 | \mathbf{x}, z] = \mathbb{E}[z^2 | \mathbf{x}]$$

Lemma

$$(\text{Baseline}) + (\text{II}) \implies$$

$$\text{Cov}(y^2, z | \mathbf{x}) = 2 \text{Cov}(y, z | \mathbf{x}) \theta_1(\mathbf{x}) - \text{Cov}(T, z | \mathbf{x}) \theta_2(\mathbf{x})$$

Corollary

$$(\text{Baseline}) + (\text{II}) + [\beta(\mathbf{x}) \neq 0] \implies [\alpha_1(\mathbf{x}) - \alpha_0(\mathbf{x})] \text{ is identified.}$$

Notice that the corollary implies that  $\beta$  is point identified if mis-classification is one-sided, as it might well be in the smoking example.

# Point Identification: 3rd Ingredient

## Assumption (III)

$$(i) \mathbb{E}[\varepsilon^2 | \mathbf{x}, z, T^*, T] = \mathbb{E}[\varepsilon^2 | \mathbf{x}, z, T^*]$$

$$(ii) \mathbb{E}[\varepsilon^3 | \mathbf{x}, z] = \mathbb{E}[\varepsilon^3 | \mathbf{x}]$$

## Lemma

(Baseline) + (II) + (III)  $\implies$

$$\text{Cov}(y^3, z | \mathbf{x}) = 3\text{Cov}(y^2 T, z | \mathbf{x})\theta_1(\mathbf{x}) - 3\text{Cov}(yT, z | \mathbf{x})\theta_2(\mathbf{x}) + \text{Cov}(T, z | \mathbf{x})\theta_3(\mathbf{x})$$

# Point Identification Result

## Theorem

(Baseline) + (II) + (III)  $\implies \beta(\mathbf{x})$  is point identified. If  $\beta(\mathbf{x}) \neq 0$ , then  $\alpha_0(\mathbf{x})$  and  $\alpha_1(\mathbf{x})$  are likewise point identified.

## Explicit Solution

$$\beta(\mathbf{x}) = \text{sign} [\theta_1(\mathbf{x})] \sqrt{3 [\theta_2(\mathbf{x})/\theta_1(\mathbf{x})]^2 - 2 [\theta_3(\mathbf{x})/\theta_1(\mathbf{x})]}$$

## Sufficient for (II) and (III)

- (a)  $T$  is conditionally independent of  $(\varepsilon, z)$  given  $(T^*, \mathbf{x})$
- (b)  $z$  is conditionally independent of  $\varepsilon$  given  $\mathbf{x}$

## Binary Regressors

## └ Point Identification Result

## Point Identification Result

## Theorem

(Baseline) + (I) + (II)  $\implies \beta(x)$  is point identified. If  $\beta(x) \neq 0$ , then  $\alpha_0(x)$  and  $\alpha_1(x)$  are likewise point identified.

## Explicit Solution

$$\beta(x) = \text{sign}[\theta_1(x)] \sqrt{3[\theta_2(x)/\theta_1(x)]^2 - 2[\theta_3(x)/\theta_1(x)]}$$

## Sufficient for (II) and (III)

- (a)  $T$  is conditionally independent of  $(x, z)$  given  $(T^*, x)$
- (b)  $z$  is conditionally independent of  $x$  given  $x$

Comment on the sufficient conditions: say that we really think these are what people have in mind in a natural experiment setting. Explain about reporting results in both logs and levels.

# Inference for a Mis-classified Regressor

## Weak Identification

- ▶  $\beta$  small  $\Rightarrow$  moment equalities uninformative about  $(\alpha_0, \alpha_1)$  [▶ more](#)
- ▶  $(\alpha_0, \alpha_1)$  could be on the boundary of the parameter space
- ▶ Also true of existing estimators that assume  $T^*$  exogenous

## Our Approach

- ▶ Sharp identified set yields *inequality* moment restrictions that remain informative even if  $\beta \approx 0$ . [▶ more](#)
- ▶ Identification-robust inference with equality and inequality MCs.

# Inference with Moment Equalities and Inequalities

## Moment Conditions

$$\mathbb{E}[m_j(\mathbf{w}_i, \vartheta_0)] \geq 0, \quad j = 1, \dots, J$$

$$\mathbb{E}[m_j(\mathbf{w}_i, \vartheta_0)] = 0, \quad j = J+1, \dots, J+K$$

## Test Statistic

$$T_n(\vartheta) = \sum_{j=1}^J \left[ \frac{\sqrt{n} \bar{m}_{n,j}(\vartheta)}{\hat{\sigma}_{n,j}(\vartheta)} \right]_-^2 + \sum_{j=J+1}^{J+K} \left[ \frac{\sqrt{n} \bar{m}_{n,j}(\vartheta)}{\hat{\sigma}_{n,j}(\vartheta)} \right]^2$$

## Critical Value

- ▶  $\sqrt{n} \bar{\mathbf{m}}_n(\vartheta_0) \rightarrow_d$  normal limit with covariance matrix  $\Sigma(\vartheta_0)$
- ▶ Use this to bootstrap the limit dist. of  $T_n(\vartheta)$  under  $H_0: \vartheta = \vartheta_0$

# Binary Regressors

## └ Inference with Moment Equalities and

## Moment Conditions

$$E[m_j(w_i, \theta_0)] \geq 0, \quad j = 1, \dots, J$$

$$E[m_j(w_i, \theta_0)] = 0, \quad j = J+1, \dots, J+K$$

## Test Statistic

$$T_n(\hat{\theta}) = \sum_{j=1}^J \left[ \frac{\sqrt{n} \hat{m}_{nj}(\hat{\theta})}{\hat{\sigma}_{nj}(\hat{\theta})} \right]^2 + \sum_{j=J+1}^{J+K} \left[ \frac{\sqrt{n} \hat{m}_{nj}(\hat{\theta})}{\hat{\sigma}_{nj}(\hat{\theta})} \right]^2$$

## Critical Value

- $\sqrt{n} \hat{m}_{nj}(\theta_0) \rightarrow_d$  normal limit with covariance matrix  $\Sigma(\theta_0)$
- Use this to bootstrap the limit dist. of  $T_n(\hat{\theta})$  under  $H_0: \theta = \theta_0$

Explain about the meaning of the m-var, the sigma-hat and the “minus” subscript

# Generalized Moment Selection

Andrews & Soares (2010)

- ▶ Inequalities that don't bind reduce power of test, so eliminate those that are “far from binding” before calculating critical value:

$$\text{Drop inequality } j \text{ if } \frac{\sqrt{n} \bar{m}_{n,j}(\vartheta_0)}{\hat{\sigma}_{n,j}(\vartheta_0)} > \sqrt{\log n}$$

- ▶ Uniformly valid test of  $H_0: \vartheta = \vartheta_0$  even if  $\vartheta_0$  is not point identified.
- ▶ Not asymptotically conservative.

## Problem

*Joint test* for the whole parameter vector but we're only interested in  $\beta$ .  
Projection is conservative and computationally intensive.

## Generalized Moment Selection

- Inequalities that don't bind reduce power of test, so eliminate those that are "far from binding" before calculating critical value:

$$\text{Drop inequality } j \text{ if } \frac{\sqrt{n} \hat{m}_{n,j}(\hat{\theta}_0)}{\hat{\sigma}_{n,j}(\hat{\theta}_0)} > \sqrt{\log n}$$

- Uniformly valid test of  $H_0: \theta = \theta_0$  even if  $\theta_0$  is not point identified.
- Not asymptotically conservative.

### Problem

Joint test for the whole parameter vector but we're only interested in  $\beta$ .

Projection is conservative and computationally intensive.

Explain what not asymptotically conservative means. Explain what projection is and why it's conservative and computationally intensive.

# Our Solution: Bonferroni-Based Inference

## Special Structure

- ▶  $\beta$  only enters MCs through  $\theta_1 = \beta / (1 - \alpha_0 - \alpha_1)$
- ▶ Strong instrument  $\Rightarrow$  inference for  $\theta_1$  is standard.
- ▶ Nuisance pars  $\gamma$  strongly identified under null for  $(\alpha_0, \alpha_1)$

## Procedure

1. Concentrate out  $(\theta_1, \gamma) \Rightarrow$  joint GMS test for  $(\alpha_0, \alpha_1)$
2. Invert test  $\Rightarrow (1 - \delta_1) \times 100\%$  confidence set for  $(\alpha_0, \alpha_1)$
3. Project  $\Rightarrow$  CI for  $(1 - \alpha_0 - \alpha_1)$
4. Construct standard  $(1 - \delta_2) \times 100\%$  IV CI for  $\theta_1$
5. Bonferroni  $\Rightarrow (1 - \delta_1 - \delta_2) \times 100\%$  CI for  $\beta$

# Binary Regressors

## └ Our Solution: Bonferroni-Based Inference

### Our Solution: Bonferroni-Based Inference

#### Special Structure

- $\beta$  only enters MCs through  $\theta_1 \approx \beta / (1 - \alpha_0 - \alpha_1)$
- Strong instrument  $\Rightarrow$  inference for  $\theta_1$  is standard.
- Nuisance pars  $\gamma$  strongly identified under null for  $(\alpha_0, \alpha_1)$

#### Procedure

1. Concentrate out  $(\theta_1, \gamma) \Rightarrow$  joint GMS test for  $(\alpha_0, \alpha_1)$
2. Invert test  $\Rightarrow (1 - \delta_1) \times 100\%$  confidence set for  $(\alpha_0, \alpha_1)$
3. Project  $\Rightarrow$  CI for  $(1 - \alpha_0 - \alpha_1)$
4. Construct standard  $(1 - \delta_2) \times 100\%$  IV CI for  $\theta_1$
5. Bonferroni  $\Rightarrow (1 - \delta_1 - \delta_2) \times 100\%$  CI for  $\beta$

Explain that the procedure works well in simulations etc. Possibly add link to simulation here.

## Example

(sim data:  $\beta = 1, \alpha_0 = 0.1, \alpha_1 = 0.2, n = 5000$ )

### 97.5% GMS Confidence Region for $(\alpha_0, \alpha_1)$

### Bonferroni Interval

1. 97.5% CI for  $(1 - \alpha_0 - \alpha_1) = (0.64, 0.82)$
2. 97.5% CI for  $\theta_1 = (1.20, 1.47)$
3.  $> 95\%$  CI for  $\beta$ :  
 $(0.64 \times 1.20, 0.82 \times 1.47) = (0.77, 1.21)$

### Comparisons

- ▶  $(0.88, 1.04)$  for IV if  $T^*$  were observed
- ▶  $(1.22, 1.45)$  for naive IV interval using  $T$

# Conclusion

## This Paper

- ▶ Partial and point identification results for effect of binary, endogenous regressor using a valid instrument.
- ▶ Identification-robust inference in models with mis-classification

# Simple Bounds for Mis-classification from First-stage

Unobserved	Observed
$p_k^*(\mathbf{x}) \equiv \mathbb{P}(T^* = 1   \mathbf{x}, z = k)$	$p_k(\mathbf{x}) \equiv \mathbb{P}(T = 1   \mathbf{x}, z = k)$

## Relationship

$$p_k^*(\mathbf{x}) = \frac{p_k(\mathbf{x}) - \alpha_0(\mathbf{x})}{1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})}, \quad k = 0, 1$$

$z$  does not affect  $(\alpha_0, \alpha_1)$ ; denominator  $\neq 0$

## Bounds for Mis-classification

$$\alpha_0(\mathbf{x}) \leq p_k(\mathbf{x}) \leq 1 - \alpha_1(\mathbf{x}), \quad k = 0, 1$$

$$\alpha_0(\mathbf{x}) + \alpha_1(\mathbf{x}) < 1$$

# What does IV estimate under mis-classification?

Unobserved

$$\beta(\mathbf{x}) = \frac{\mathbb{E}[y|\mathbf{x}, z = 1] - \mathbb{E}[y|\mathbf{x}, z = 0]}{p_1^*(\mathbf{x}) - p_0^*(\mathbf{x})}$$

Wald (Observed)

$$\frac{\mathbb{E}[y|\mathbf{x}, z = 1] - \mathbb{E}[y|\mathbf{x}, z = 0]}{p_1(\mathbf{x}) - p_0(\mathbf{x})} = \beta(\mathbf{x}) \left[ \frac{p_1^*(\mathbf{x}) - p_0^*(\mathbf{x})}{p_1(\mathbf{x}) - p_0(\mathbf{x})} \right] = \frac{\beta(\mathbf{x})}{1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})}$$

$$p_1^*(\mathbf{x}) - p_0^*(\mathbf{x}) = \frac{p_1(\mathbf{x}) - \alpha_0(\mathbf{x})}{1 - \alpha_0 - \alpha_1(\mathbf{x})} - \frac{p_0(\mathbf{x}) - \alpha_0(\mathbf{x})}{1 - \alpha_0 - \alpha_1(\mathbf{x})} = \frac{p_1(\mathbf{x}) - p_0(\mathbf{x})}{1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})}$$

## Partial Identification Bounds for $\beta(\mathbf{x})$

$$\beta(\mathbf{x}) = [1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x})] \left[ \frac{\mathbb{E}[y|\mathbf{x}, z = 1] - \mathbb{E}[y|\mathbf{x}, z = 0]}{p_1(\mathbf{x}) - p_0(\mathbf{x})} \right]$$

$$0 \leq \alpha_0 \leq \min_k \{p_k(\mathbf{x})\}, \quad 0 \leq \alpha_1 \leq \min_k \{1 - p_k(\mathbf{x})\}$$

### No Mis-classification

$$\alpha_0(\mathbf{x}) = \alpha_1(\mathbf{x}) = 0 \implies \beta(\mathbf{x}) = \text{Wald}$$

### Maximum Mis-classification

$$\alpha_0(\mathbf{x}) = p_{\min}(\mathbf{x}), \quad \alpha_1(\mathbf{x}) = 1 - p_{\max}(\mathbf{x})$$

$$\implies 1 - \alpha_0(\mathbf{x}) - \alpha_1(\mathbf{x}) = p_{\max}(\mathbf{x}) - p_{\min}(\mathbf{x}) = |p_1(\mathbf{x}) - p_0(\mathbf{x})|$$

$$\implies \beta(\mathbf{x}) = \text{sign}\{p_1(\mathbf{x}) - p_0(\mathbf{x})\} \times (\text{Reduced Form})$$

# Just-Identified System of Moment Equalities

Suppress dependence on  $\mathbf{x} \dots$

$$\mathbb{E} \left[ \{ \boldsymbol{\Psi}(\boldsymbol{\theta}) \mathbf{w}_i - \boldsymbol{\kappa} \} \otimes \begin{pmatrix} 1 \\ z \end{pmatrix} \right] = \mathbf{0}$$

$$\boldsymbol{\Psi}(\boldsymbol{\theta}) \equiv \begin{bmatrix} -\theta_1 & 1 & 0 & 0 & 0 & 0 \\ \theta_2 & 0 & -2\theta_1 & 1 & 0 & 0 \\ -\theta_3 & 0 & 3\theta_2 & 0 & -3\theta_1 & 1 \end{bmatrix}$$

$$\mathbf{w}_i = (T_i, y_i, y_i T_i, y_i^2, y_i^2 T_i, y_i^3)' \quad \theta_1 = \beta / (1 - \alpha_0 - \alpha_1)$$

$$\boldsymbol{\kappa} = (\kappa_1, \kappa_2, \kappa_3)' \quad \theta_2 = \theta_1^2 (1 + \alpha_0 - \alpha_1)$$

$$\theta_3 = \theta_1^3 [(1 - \alpha_0 - \alpha_1)^2 + 6\alpha_0(1 - \alpha_1)]$$

## Moment Inequalities I – First-stage Probabilities

$\alpha_0 \leq p_k \leq 1 - \alpha_1$  becomes  $\mathbb{E}[m(\mathbf{w}_i, \boldsymbol{\vartheta})] \geq \mathbf{0}$  for all  $k$  where

$$m(\mathbf{w}_i, \boldsymbol{\vartheta}) \equiv \begin{bmatrix} \mathbf{1}(z_i = k)(T - \alpha_0) \\ \mathbf{1}(z_i = k)(1 - T_i - \alpha_1) \end{bmatrix}$$

## Moment Inequalities II – Non-differential Assumption

For all  $k$ , we have  $\mathbb{E}[m(\mathbf{w}_i, \vartheta, \mathbf{q}_k)] \geq 0$  where

$$m(\mathbf{w}_i, \vartheta, \mathbf{q}_k) \equiv \begin{bmatrix} y_i \mathbf{1}(z_i = k) \left\{ (T_i - \alpha_0) - \mathbf{1}(y_i \leq \underline{q}_{0k})(1 - T_i) \left( \frac{1 - \alpha_0 - \alpha_1}{\alpha_1} \right) \right\} \\ -y_i \mathbf{1}(z_i = k) \left\{ (T_i - \alpha_0) - \mathbf{1}(y_i > \bar{q}_{0k})(1 - T_i) \left( \frac{1 - \alpha_0 - \alpha_1}{\alpha_1} \right) \right\} \\ y_i \mathbf{1}(z_i = k) \left\{ (T_i - \alpha_0) - \mathbf{1}(y_i \leq \underline{q}_{1k}) T_i \left( \frac{1 - \alpha_0 - \alpha_1}{1 - \alpha_1} \right) \right\} \\ -y_i \mathbf{1}(z_i = k) \left\{ (T_i - \alpha_0) - \mathbf{1}(y_i > \bar{q}_{1k}) T_i \left( \frac{1 - \alpha_0 - \alpha_1}{1 - \alpha_1} \right) \right\} \end{bmatrix}$$

and  $\mathbf{q}_k \equiv (\underline{q}_{0k}, \bar{q}_{0k}, \underline{q}_{1k}, \bar{q}_{1k})'$  defined by  $\mathbb{E}[h(\mathbf{w}_i, \vartheta, \mathbf{q}_k)] = 0$  with

$$h(\mathbf{w}_i, \vartheta, \mathbf{q}_k) = \begin{bmatrix} \mathbf{1}(y_i \leq \underline{q}_{0k}) \mathbf{1}(z_i = k)(1 - T_i) - \left( \frac{\alpha_1}{1 - \alpha_0 - \alpha_1} \right) \mathbf{1}(z_i = k)(T_i - \alpha_0) \\ \mathbf{1}(y_i \leq \bar{q}_{0k}) \mathbf{1}(z_i = k)(1 - T_i) - \left( \frac{1 - \alpha_0}{1 - \alpha_0 - \alpha_1} \right) \mathbf{1}(z_i = k)(1 - T_i - \alpha_1) \\ \mathbf{1}(y_i \leq \underline{q}_{1k}) \mathbf{1}(z_i = k) T_i - \left( \frac{1 - \alpha_1}{1 - \alpha_0 - \alpha_1} \right) \mathbf{1}(z_i = k)(T_i - \alpha_0) \\ \mathbf{1}(y_i \leq \bar{q}_{1k}) \mathbf{1}(z_i = k) T_i - \left( \frac{\alpha_0}{1 - \alpha_0 - \alpha_1} \right) \mathbf{1}(z_i = k)(1 - T_i - \alpha_1) \end{bmatrix}$$
